PART E: PEER CODE REVIEW EVALUATION

1. Strengths of the Refactored Code

• The code uses a class to encapsulate the dynamic array and its operations, reducing the problems caused by global variables.

2. Weaknesses / Areas for Improvement

• The matrix function still uses a fixed 3x3 matrix, so it is not very flexible.
• The class disables copying instead of implementing a complete copy and move system. A reusable class could follow the Rule of Five.

3. Recommendations

• Use std::vector when manual dynamic memory management is not specifically required.
• Add useful functions such as clear(), reserve(), or capacity-management functions if the system becomes larger.

4. Overall Evaluation

• The refactored code is a significant improvement over the original legacy version. The major memory leak, unsafe index access, off-by-one error, and redundant loops were corrected.
